

Marine Bivalvia (Mollusca) of Guam

GUSTAV PAULAY¹

*Marine Laboratory
University of Guam
Mangilao, Guam 96923 USA*

Abstract—The marine bivalves of Guam are documented from new collections and 339 species recorded. Nevertheless Guam's fauna remains imperfectly known and is estimated to be considerably more diverse. Such high diversity on a local scale in the west-central Pacific suggests that bivalve diversity in the Indo-west Pacific is much higher than previously recorded. Pteriomorphs and heterodonts dominate Guam's fauna, while protobranchs and anomalodesmatans comprise only four species. Galeommatids represent the most species rich family, even though they are uncommon in samples.

Introduction

REGIONAL SETTING

Guam (13°N, 144°W), the southernmost of the Mariana Islands, is the largest, most populous, and developed island in Micronesia. As part of the island arc bordering the northwestern margin of the Pacific plate, Guam has had a complex geological history since initiation around 42 Ma. Submarine and subaerial volcanic episodes interspersed with periods of sedimentation and reef formation, together with alternating subsidence and uplift have led to complex physiography both above and below water. Northern Guam is a relatively flat, uplifted limestone plateau, bordered by karstic cliffs and limited reef development. In contrast southern Guam is dominated by volcanic hills, locally with limestone veneers, with some valleys terminating in small bays. Barrier reefs are limited to shallow Cocos lagoon at the southern tip of the island, and Apra Harbor at the junction of the volcanic south and karstic north (Fig. 1). Other than these two small lagoons, Guam's shore is fronted by fringing reefs or lacks reef protection.

Guam has a diversity of marine habitats, even if it lacks the large and complex lagoons that characterize many Micronesian islands to the south. Major habitats include exposed limestone shores without reef protection, supratidal benches, narrow, intertidal reef flats, fringing reefs with well developed (1-3 m deep) moats, and shallow (<12 m) Cocos and deep (60 m) Apra Harbor lagoons. A gradient of southwardly increasing fringing reef development appears to be partly the result of greater tectonic uplift toward the north. Reef development is

¹Current address: Florida Museum of Natural History, Gainesville FL 32611-7800 USA, email: paulay@flmnh.ufl.edu

under further local geological control, with large embayments, created by faulting and groundwater discharge in Tumon, Hagåtña (Agaña) and Pago bays, having developed the widest fringing reefs, and with a barrier reef (Apra Harbor) developed north of the projecting Orote peninsula. Additional variation in reef habitats result from differences in wind, wave, and current exposure, with eastern reefs considerably more exposed than western reefs to both tradewinds and typhoons. Finally, terrigenous sediments are limited to the south, most prevalent along the southwest coast, and this is reflected in the localization of several infaunal bivalve species. Fore reefs exhibit moderate variation around the island in width, terracing, and in the abundance and nature of mobile sediments. Mangroves are limited to very small stands in stream estuaries, and to larger, but still narrow bands in inner Apra Harbor and at the southeast end of the island in Merizo. Seagrass beds are developed along the larger fringing reef systems as well as in Cocos lagoon.

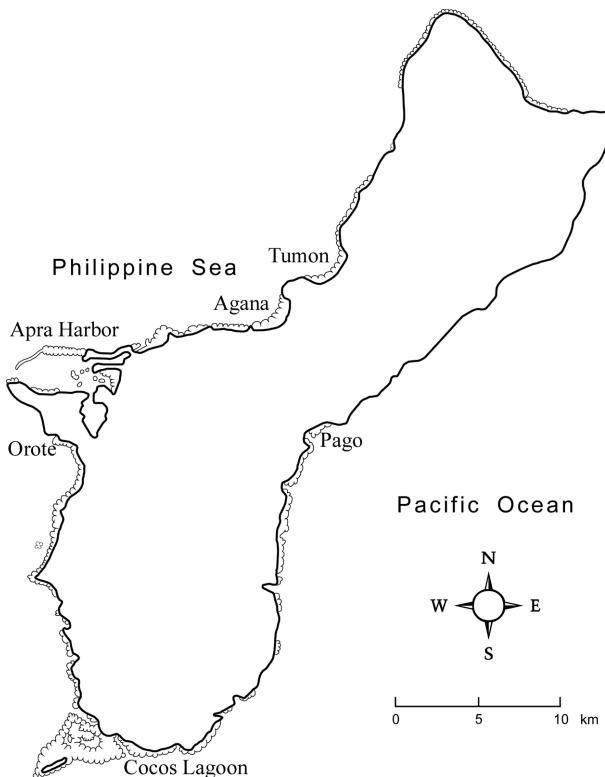

Figure 1. Map of Guam.

Apra Harbor, the largest and busiest port in Micronesia, is the only deep lagoon in the Marianas. Its unique habitats host many species not found

elsewhere on Guam or in the Marianas. The harbor is also the main entry point for species introduced by shipping traffic (Paulay et al. 2002). Apra Harbor has been substantially altered following World War II, as a large breakwater built over the barrier reef and bank that previously bounded the lagoon along the north has substantially reduced circulation with the surrounding ocean. Despite such major alterations, Apra Harbor has a vibrant and thriving marine biota, with well-developed reefs, some of the highest coral cover (albeit dominated by *Porites rus*) on Guam, and a diverse biota. Physical, chemical, and biotic conditions all show pronounced east to west gradients in the harbor, related to the unidirectional exchange of water through the western entrance. Benthic habitats range from fairly exposed and oceanic reefs along the northwestern end of the Orote Peninsula, to silt-choked, lagoonal patch reefs, mud and silty sand bottoms, and mangroves in Sasa Bay and the Inner Harbor, with corresponding variation in the biota.

BIVALVES

Mollusks are among the taxonomically better known phyla, partly because shells have long fascinated naturalists, are often sufficient in themselves for species level identification, and persist and accumulate after the animal's death. Shells provide more abundant material for study, and a better cross section of what lives in an area, than is available for most organisms, which can only be studied alive. The study of Indo-West Pacific bivalves is nevertheless hampered by the diversity of the fauna and paucity of revisionary studies. The publication of several regional faunistic monographs (Oliver 1992, 1995, Lamprell & Whitehead 1992, Lamprell & Healy 1998, Okutani 2000) and taxonomic revisions (e.g., Willan 1993, Vidal 1999, Glover & Taylor 2001), have greatly facilitated taxonomic work on Indo-West Pacific bivalves in the past decade. Nevertheless this diverse class remains poorly known. Although many, especially smaller bivalves remain undescribed, a perhaps greater limitation for faunistic studies is the profusion of inadequately described taxa and consequent abundance of junior synonyms that have resulted from the ready availability and attraction of shells. Revisionary studies are badly needed for most families to stabilize both species level nomenclature and generic and higher classification.

The bivalves of Guam have received little attention in the past. Species from the island have been included in some revisions (e.g., Stenzel 1971, Rosewater 1961, 1965, Waller 1972, Willan 1993, Vidal 1993, 1997, 1999), and one species was described from Guam (Raines 1996). Several M.S. theses at the University of Guam focused on bivalves (Jameson 1975, Day 1977, Braley 1981, Persselin 1998, Peshut 2000). The mollusks of the Northern Mariana Islands, but not Guam, were checklisted by Vermeij et al. (1983), while Cloud (1959) recorded 48 species from Saipan. Checklist attempts for Guam began with Smith (1986), who listed 65 species, while Paulay (1996a) recorded 201 species, and Peshut (2000) encountered 223 taxa in a quantitative survey. I have been incidentally collecting and identifying bivalves on Guam since 1991, but attention paid to the

comprehensive marine biodiversity survey featured in this volume has limited effort spent specifically on bivalves. The present checklist is thus more a report of progress to date than an authoritative list of the fauna. Nevertheless it already demonstrates the substantial local diversity of the group. Other than the 20 sediment samples (500+ specimens each) picked by Peshut (2000) and ca. 20 dredge hauls from 50-150 m depths fully sorted for bivalves, bivalve collecting has been incidental to other work. Taxonomic determinations remain preliminary, with many species identified to generic level only. Accurate species level identifications in bivalves often require mini revisions of relevant taxa.

Methods

Bivalves were collected from beaches, reef flats, moats, lagoons, fore reefs, and the lower reef talus to ca. 200m by walking, snorkeling, SCUBA, and dredging. Dredging was largely confined to 50-150m depths, focused on a well-developed terrace at that depth around the island. Epifaunal and endolithic species were collected from reef substrata, while dead shells and infaunal bivalves were taken by fanning sand during dives and from sediment samples retained on 0.8mm mesh sieves (see Peshut 2000). I have examined ~15,000 specimens, although over 80% of these came from fewer than 40 sediment and dredge samples.

The extent of coverage varies with macrohabitat as well as microhabitat. Coverage is relatively good on the leeward deep slope and on fringing reefs. It is moderate on the fore reef at diving depths, in Apra Harbor, and on the windward deep slope. Endolithic taxa have received little attention, as have cemented, epibenthic species. Unidentified taxa are given consecutive numbers in my notes, these are used here as they apply to Guamanian taxa. Literature records are included where available. Records from other Mariana Islands were not systematically searched, although are included when they are based on specimens seen or from reliable literature.

Results & Discussion

At present 339 species of bivalves are known from Guam (Appendix 1). Because considerable effort was placed on picking shells from sediment retained on a 0.8mm mesh, microbivalves are at least as well documented as larger species. Nevertheless new records are still commonly encountered: almost every sediment sample processed included species previously unrecorded from Guam. Given that sampling was virtually confined to <200m and remains modest there, the entire bivalve fauna of the island is likely considerably greater than 500 species.

Such richness underscores Bouchet et al.'s (2002) observation that the Indo-West Pacific mollusk fauna is considerably more diverse than previously recognized. The highest currently documented regional bivalve diversity in the

world is around 1200 species (Crame 2000), in the Southeast Asian – Indo-Malayan region. Species richness rapidly decreases eastward from this diversity center in most marine organisms (Paulay 1997). In comparison to these regional diversities, the local species richness of bivalves on Guam is remarkable, considering the location and small size of the island, limited habitat diversity, and limited extent of coverage, especially with regard to depth. Bouchet et al. (2002) documented very high mollusk diversity in a 5 X 5 km area in Koumac, New Caledonia, with 519 species of bivalves recorded. Their results were based on a sample size ($N = 45,480$) ca. three times greater than in the present study, from an island with substantially greater habitat diversity than Guam. An interesting comparison can be made between the opisthobranch fauna of Koumac (271 species) and Guam (485 species; Carlson & Hoff 2003). Opisthobranchs have been more exhaustively sampled on Guam than any other mollusk group. As a group they are also more difficult to sample in rapid biodiversity surveys than shelled taxa like bivalves, because most species can only be collected alive. These comparisons suggest that Guam's bivalve biota remains substantially undersampled. It further implies that the species richness of bivalves in the still poorly-explored Indo-Malayan diversity center is likely much higher than heretofore documented. Preliminary samples from the area indeed suggest very high species richness, especially when microbivalves are considered.

Pteriomorphs and heterodonts dominate Guam's fauna (Table 1), while protobranchs and anomalodesmatans are represented by just 4 species. Dominance of these two subclasses is typical for shallow-water, tropical Pacific island bivalve faunas (Paulay 1990). 46 families were encountered, 9 with >10 species, while 23 families were represented by 1 or 2 species each (Table 2). In comparison, Bouchet et al. (2002) encountered 62 families at Koumac, New Caledonia, 14 with >10 species, and 27 with 1 or 2 species. The rankings of families in terms of species diversity are similar between Guam and New Caledonia (Tables 2). The main overall difference is that infaunal taxa are proportionately more diverse than epifaunal taxa in New Caledonia relative to Guam. Thus the ratio between the predominantly infaunal heterodonts and predominantly epifaunal pteriomorphs is 1.99 for New Caledonia and 1.56 for Guam. This difference reflects the different nature of reef habitats at these locations, with a very wide, soft-bottom-dominated lagoon enclosed by the barrier reef at Koumac compared with limited fringing reef development giving way to a hard-bottom-dominated fore reef environment on Guam.

The Galeommatidae sensu lato (cf. Ponder 1998) stand out in both samples as a megadiverse group. Their actual diversity must be substantially higher than indicated in Table 3, and could be several times higher than that of any other family. Galeommatid shells are relatively uncommon in samples, and many species are currently known from one or a few valves on Guam. Similarly, at Koumac galeommatids accounted for only 1.6% of the shells, but 12% of the species diversity (Bouchet et al. 2002). Their rarity is likely in part a preservational artifact, as shells are often exceptionally fragile, and in part an

ecological / collecting issue, as many species live in specialized microhabitats, often in commensal association with varied invertebrate hosts. Such a combination of rarity and diversity implies that the known diversity of this group will grow rapidly and substantially when larger samples become available. Galeommatids are poorly known taxonomically, with generic and even higher taxonomic limits poorly understood, and much if not most of their indicated diversity may be in undescribed species (Morton & Scott 1989).

Table 1. Species richness of bivalve subclasses on Guam and New Caledonia

Clade	Guam	Koumac, NC
Protobranchia	1	2
Pteriomorpha	131	165
Heterodonta	204	329
Anomalodesmata	3	21

Data for Koumac, New Caledonia from Bouchet et al. (2002)

At least 10 of the bivalve species documented appear no longer to survive on Guam. Locally extirpated taxa include 3 intentionally (*Crassostrea gigas*, *Saccostrea tuberculata*, *Tridacna gigas*) and 3 accidentally introduced species (*Anomia nobilis*, *Chama fibula*, *Chama macerophylla*), 3 indigenous species from Apra Harbor (*Lopha cristagalli*, *Timoclea* sp. 9, *Spondylus varius*) and the previously widespread *Hippopus hippopus*. The last two species were probably collected to death, *S. varius* for curios following WWII, while *Hippopus* prehistorically, presumably for food. The other two indigenous species may have succumbed to environmental change in Apra Harbor.

Table 2. Most species rich bivalve families on Guam and New Caledonia

Family	Guam # of species	Guam % of fauna	Koumac, NC # of species	Koumac, NC % of fauna
Galeommatidae s. l.	39	11%	61	12%
Tellinidae	38	11%	51	10%
Cardiidae ¹	29	9%	37	7%
Veneridae	28	8%	53	10%
Limidae	21	6%	15	3%
Pectinidae	21	6%	27	5%
Arcidae	19	6%	24	5%
Mytilidae	18	5%	27	5%
Lucinidae	17	4%	20	4%

Species richness of families with >10 species on Guam compared with Koumac, New Caledonia (Bouchet et al. 2002). The other families in the New Caledonian sample that had >10 species are: Semelidae (19), Spondylidae (16), Psammobiidae (13), Pteriidae (12), and Mactridae (11).

¹includes Tridacnidae of Bouchet et al. 2002.

Acknowledgements

I thank the students, faculty, and staff of the University of Guam Marine Lab for help with documenting the bivalves of Guam. Special thanks to Harry Conley, Vince Diego, Lisa Kirkendale, Ismael Perez, Sara Persselin, John Starmer, Linda Ward and especially Pete Peshut for collecting bivalves, Barry Smith for setting the stage, Frank Cushing for dredging, and Rob Myers for use of his photos. Thanks also to Joe Carter, Aki Matsukuma, Paul Scott, John Taylor, Jacques Vidal, and Tom Waller, for help with identifications. Funding by NOAA (Insular Pacific Marine Research Program), U.S. Dept. of Defense at COMNAVMARIANAS, and SeaGrant (SG-NIS-35) are gratefully acknowledged. Contribution 492 of the University of Guam Marine Laboratory.

Notes:

- 1) Subfossil remains of Holocene age of these species are widespread on Guam, however extant populations are largely restricted to inner Apra Harbor. This restriction may correspond to reduction of mangrove habitats during the Holocene (Amesbury 1999).
- 2) Generic assignments tentative, needs revision.
- 3) May correspond to Hayami & Kase's (1996) record of *Bentharca* sp. B from Guam.
- 4) May correspond to Hayami & Kase's (1996) record of *Bentharca tenuis*? from Guam.
- 5) A minute, undescribed, arcoïd bivalve tentatively assigned to the Limopoidea by Hayami & Kase (1993).
- 6) Based on sight record by GP, no voucher currently available for this abundant species.
- 7) Indo-West Pacific *Malleus* (*Maiyifundus*) species have been over-synonymized. The Guam species is closest to the Hawaiian *M. nuttalli*, which, contrary to current usage, is not a synonym of *M. regula*.
- 8) Known only from Apra Harbor, where this species inhabited steep reef faces. Although dead shells are still encountered, no live animals have been seen in years, and this giant spondylid appears to have been extirpated, probably by overcollecting. Based on sight record by GP.
- 9) This species was described from Hawaii, where it is common in Pearl Harbor and potentially introduced. It was brought to Guam on the dry dock Machinist in July, 1999. Most animals died within a month of arrival, so the species is unlikely to become established on Guam.
- 10) Anomids remain unstudied on Guam due to limited well-preserved material on hand.

- 11) These species are undescribed members of a clade of minute dimyids, with well developed hinge teeth, that occur in reef caves throughout the Indo-West Pacific.
- 12) *Domyella* sp. B of Hayami & Kase (1996).
- 13) Often incorrectly identified as *C. concentricus* (e.g., Okutani 2000).
- 14) Introduced to Apra Harbor Guam (see Eldredge 1994), but appears not to have become established.
- 15) As *Ostrea nomades* in Braley (1984); synonymy after Lamprell & Healy (1998).
- 16) Known only from dead shells in Apra Harbor dredgings, never seen alive on Guam.
- 17) Introduced to Apra Harbor, Guam (see Braley 1984 and Eldredge 1994).
- 18) As *Saccostrea cucullata tuberculata* in Braley (1984); introduced to Guam.
- 19) Brought to Guam from Hawaii on the dry dock Machinist in July, 1999. Most animals died within a month of arrival, so the species is unlikely to establish on Guam.
- 20) Kilburn & Rippey (1982) and Paulay (1987, 1989) have previously referred to this species as *Chama limbula* Lamarck, 1819. I have since seen Lamarck's types and they do not match this common Indo-West Pacific species well. *Chama tostoma* is the oldest clearly valid name.
- 21) This West Atlantic species was brought to Guam from Hawaii on the dry dock Machinist in July, 1999 in great abundance. Most animals died within a month of arrival, so the species is unlikely to become established on Guam.
- 22) This species is extirpated on Guam, although Holocene shells are occasionally found. The only living individual recorded (UGI 1892) was taken in Apra Harbor near the docks and is suspected to have been dropped off a boat after being brought from another island.
- 23) Known only from worn, mostly small (<1cm) shells from deep (~100m) water. Whether these represent an extant deep-water population or a now extirpated population from the glacial low stand is not known. Similar small *Lumulicardia* are commonly dredged deep from the lagoons of the Marshall Islands (USNM collections).
- 24) Introduced from Palau. The introduced animals are still alive (see photo cited), but no recruitment has been observed.
- 25) An attempt to introduce *T. gigas* to Guam (Eldredge 1994) was apparently not successful. This species has a Pleistocene fossil record on Guam, but the population appears to have died out before the arrival of people, perhaps during a glacial low stand, as no Holocene shells are known (Paulay 1996b).
- 26) *Semelangulus* sp. 3 of Paulay (1996b); A. Matsukuma (in prep.) considers *Semelangulus* to be a junior synonym of *Exotica*.
- 27) *Semelangulus* sp. 1 of Paulay (1990); not 26.
- 28) *Semelangulus* sp. 2 of Paulay (1990) and *Semelangulus crebrimaculatus* of Paulay (1996b), not Sowerby, 1868; see not 26.
- 29) Known from a single, dead sample of worn shells only, from the Piti reef flat. This species is common in atoll lagoons through much of the western Pacific.
- 30) Known from a single, fresh valve on Guam collected on the leeward fore reef.
- 31) Although this surf clam is abundant on most islands where it occurs, it is rare on Guam and has not been seen alive in the past decade.
- 32) As *C. hyalina* in Hayami & Kase (1996), which may be a valid name for some specimens. The considerable morphological variation in *Coralliophaga* has been attributed to their endolithic lifestyle, and only two Indo-West Pacific species were recognized in the last revision (Solem 1954). The possibility that additional cryptic diversity may underlie this variation is worth investigating.

- 33) A small species that must have been extremely abundant in inner Apra Harbor some time in the past, but I have never seen it alive. When the Inner Harbor was excavated after WWII, dredge spoils were deposited around Rizal Beach in northern Agat Bay. *Timoclea* sp. 1 shells washed out of these spoils now form a shell hash on large beach areas here and we have even been collected offshore in the area as well. Numerous other mollusks (e.g., *Spondylus multimuricatus*, *Lopha cristagalli*, *Chama brassica*) as well as fossil crabs have also washed out of harbor dredge spoils in this area. See Kesling (1958) for a review of the origin of these deposits.
- 34) As *Teredo diegensis* in Edmondson (1946); as *Teredo yaesui* in Roch (1976); synonymy after Turner (1966).
- 35) As *Teredo juttingae* in Roch (1976); synonymy after Turner (1966).
- 36) As *Teredo trulliformis* in Edmondson (1946); synonymy after Turner (1966).
- 37) As *Teredo bensonii* in Edmondson (1946) and Roch (1976); synonymy after Turner (1966).
- 38) As *Teredo matocorana* in Roch (1976); generic assignment after Turner (1966).
- 39) *Pecten coruscans* Hinds, 1845, currently assigned to *Semipallium*, differs from other members of the genus in developing directly from the prodissococonch to the radially plicate stage, without depositing an intervening prismatic shell layer in the early dissococonch of the right valve (Waller 1972). *Pascahinmites* is an available generic name for this lineage, erected for *Pecten pasca* Dall, 1908, an Easter Island endemic offshoot from *coruscans* stock. Although *Pascahinmites* was erected because of the cemented lifestyle of *pasca* (Dijkstra & Raines 1999), the lack of an external prismatic layer in the early right dissococonch is the diagnostic character of the genus (T.R. Waller pers. comm. 2002).
- 40) Misidentified as *Asaphis deflorata* in Hidalgo (1904-1905), an Atlantic congener.
- 41) All classified as *Tellina* in Hidalgo (1904-1905).
- 42) As *Tellina rhomboides* in Hidalgo (1904-1905), synonymy after Lamprell & Whitehead (1992).
- 43) As *Tellina rugosa* in Hidalgo (1904-1905), synonymy after Kay (1979).
- 44) Classified as *Arcopagia* in Hidalgo (1904-1905).
- 45) As *Caryatis obliquata* in Hidalgo (1904-1905), synonymy after Lamprell & Whitehead (1992).
- 46) Classified as *Crista pectinata* in Hidalgo (1904-1905).
- 47) Classified as *Venus* in Hidalgo (1904-1905).
- 48) Classified as *Hemicardium* in Hidalgo (1904-1905).
- 49) As *Tridacna mutica* in Hidalgo (1904-1905), synonymy after Rosewater (1965).
- 50) Classified as *Corbis* in Hidalgo (1904-1905).
- 51) As *Lucina fibula* in Hidalgo (1904-1905), synonymy after Lamprell & Whitehead (1992).
- 52) Classified as *Lucina* in Hidalgo (1904-1905).
- 53) Hidalgo's (1904-1905) record of *Perna anomioides* may pertain to this species, or to *Isognomon perna*.
- 54) Classified as *Chlamys* in Hidalgo (1904-1905).
- 55) Classified as *Modiolia striatula* in Hidalgo (1904-1905).
- 56) As *Arca volucris* in Hidalgo (1904-1905), synonymy after Lamprell & Healy (1998).
- 57) Hidalgo's (1904-1905) record of *Venericardia canaliculata* Reeve needs to be verified and is not included.
- 58) Raines (1996) also records *Semipallium tigris* from Guam, but I have never seen any specimens of that species on the island.
